

UMTS

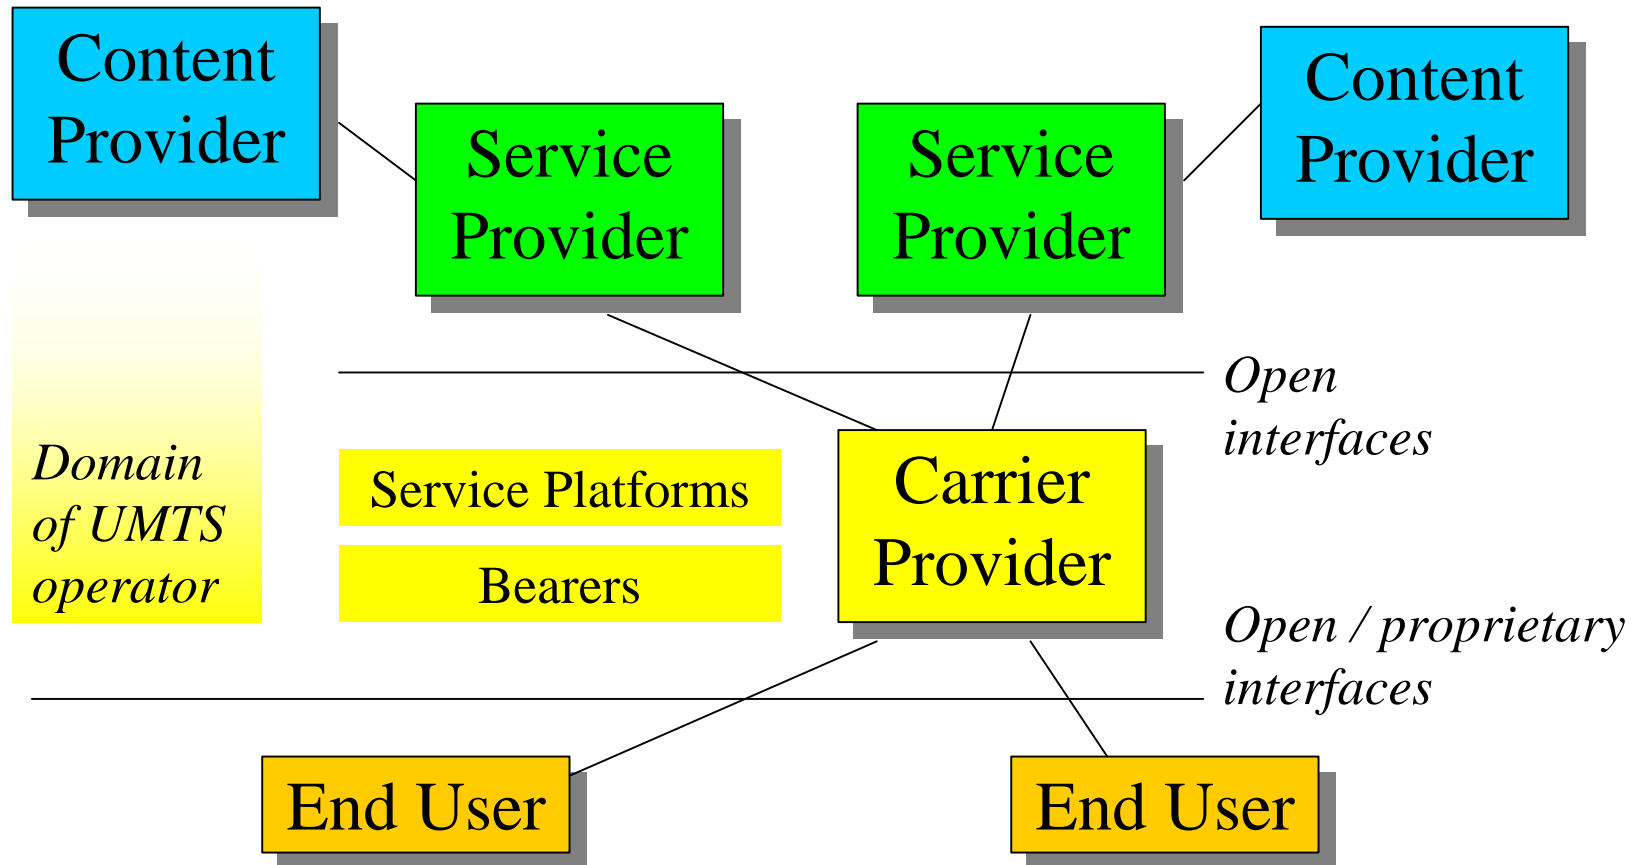

- Part of the IMT 2000 "family"
- 3rd Generation digital cellular mobile system
- Approximately "old" (GSM + GPRS) core network + "new" radio access network (UTRAN) including "new" radio interface (WCDMA)
- New service standardisation approach
- 3GPP Specifications (www.3gpp.org)

New service standardisation approach

Existing systems have largely standardised the teleservices, applications and supplementary services which they provide. As a consequence, substantial re-engineering is required to enable new services to be provided.

3GPP therefore standardises **service capabilities** and not the services themselves. Service capabilities consist of **bearers** defined by **QoS parameters** and the mechanisms needed to realise services. These mechanisms include the functionality provided by various network elements, the communication between them and the storage of associated data.

UMTS Service Model

CAMEL (2G & 3G)

CAMEL feature (Customised Applications for Mobile network Enhanced Logic) is a set of “IN” type functions and procedures that make operator-specific services available to subscribers who roam outside their home network.

CAMEL is more than a set of supplementary services
CAMEL = IN technology + global mobility

CAMEL Service Environment (CSE) is a logical entity in the subscriber's home network which processes IN related procedures

CSE » SCP in home network

CAMEL Phase 1

Circuit switched call-related IN procedures

1. Call control proceeds up to MSC

2. Trigger activated in basic call state model at SSP →

3. SSP requests information from CSE

4. CSE provides information

5. Call control continues

Typical triggers:

Calling number

Called number

Cell ID

CAMEL Phase 2

Non-call-related procedures possible

- 1. Call control proceeds as normal*
- 2. Call control is interrupted (e.g. for announcement)*
- 3. Call control resumes*

Typical application:

*In prepaid service:
"your prepaid account
is approaching zero"*

CAMEL Phase 3

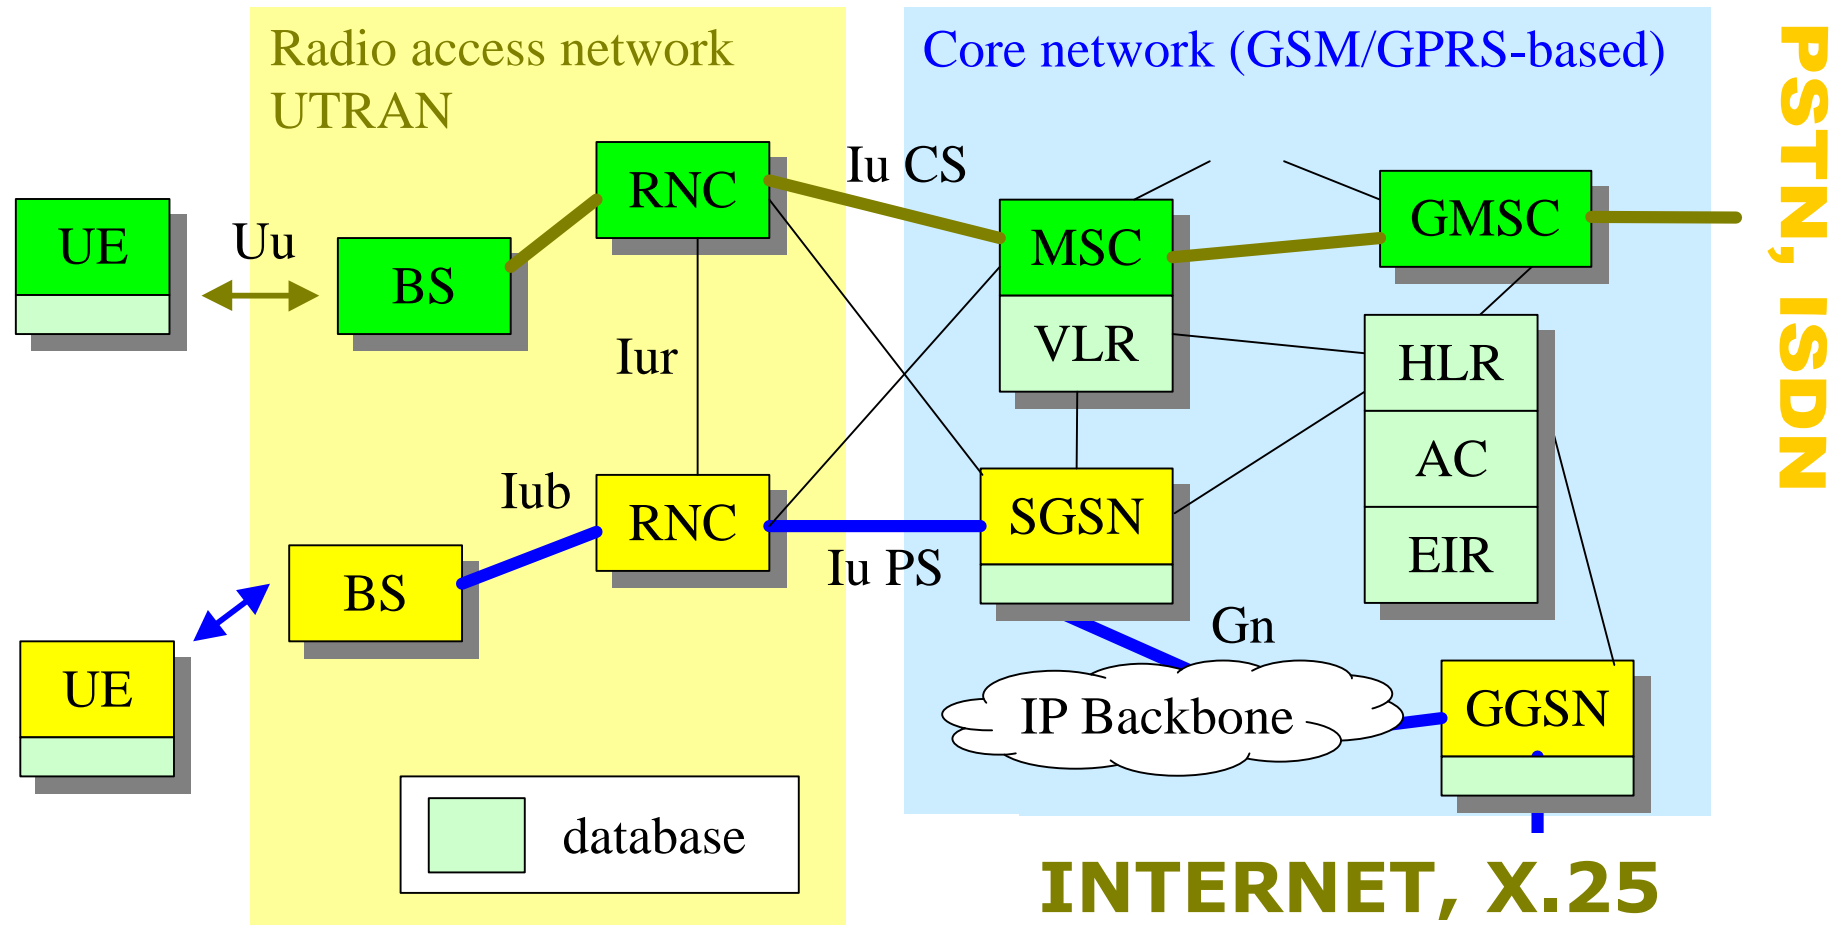

IN functionality is extended to include packet switched sessions...

Virtual Home Environment (VHE)

Same subscriber profile & charging/numbering information in any UMTS network (this is not easy to implement!)

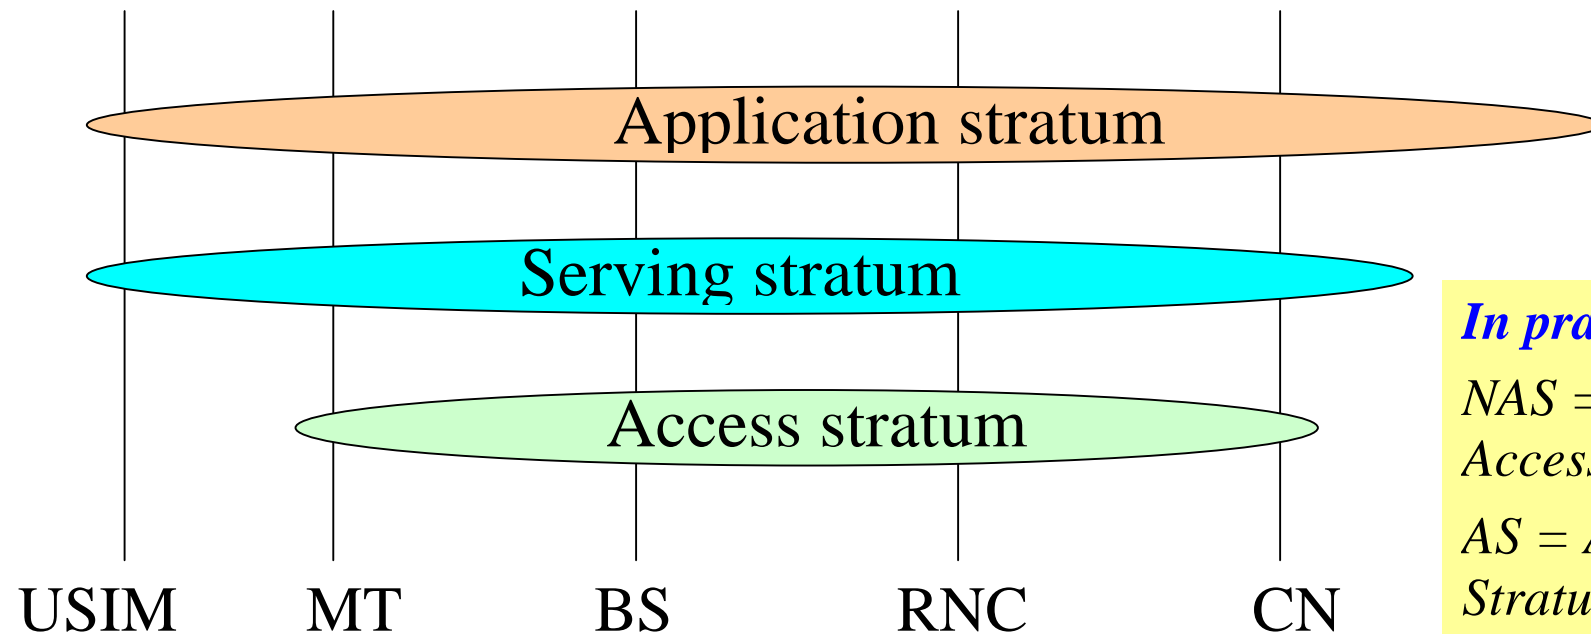

UMTS network architecture

UMTS "stratum" concept

Stratum: Grouping of protocols related to one aspect of the services provided by one or several domains

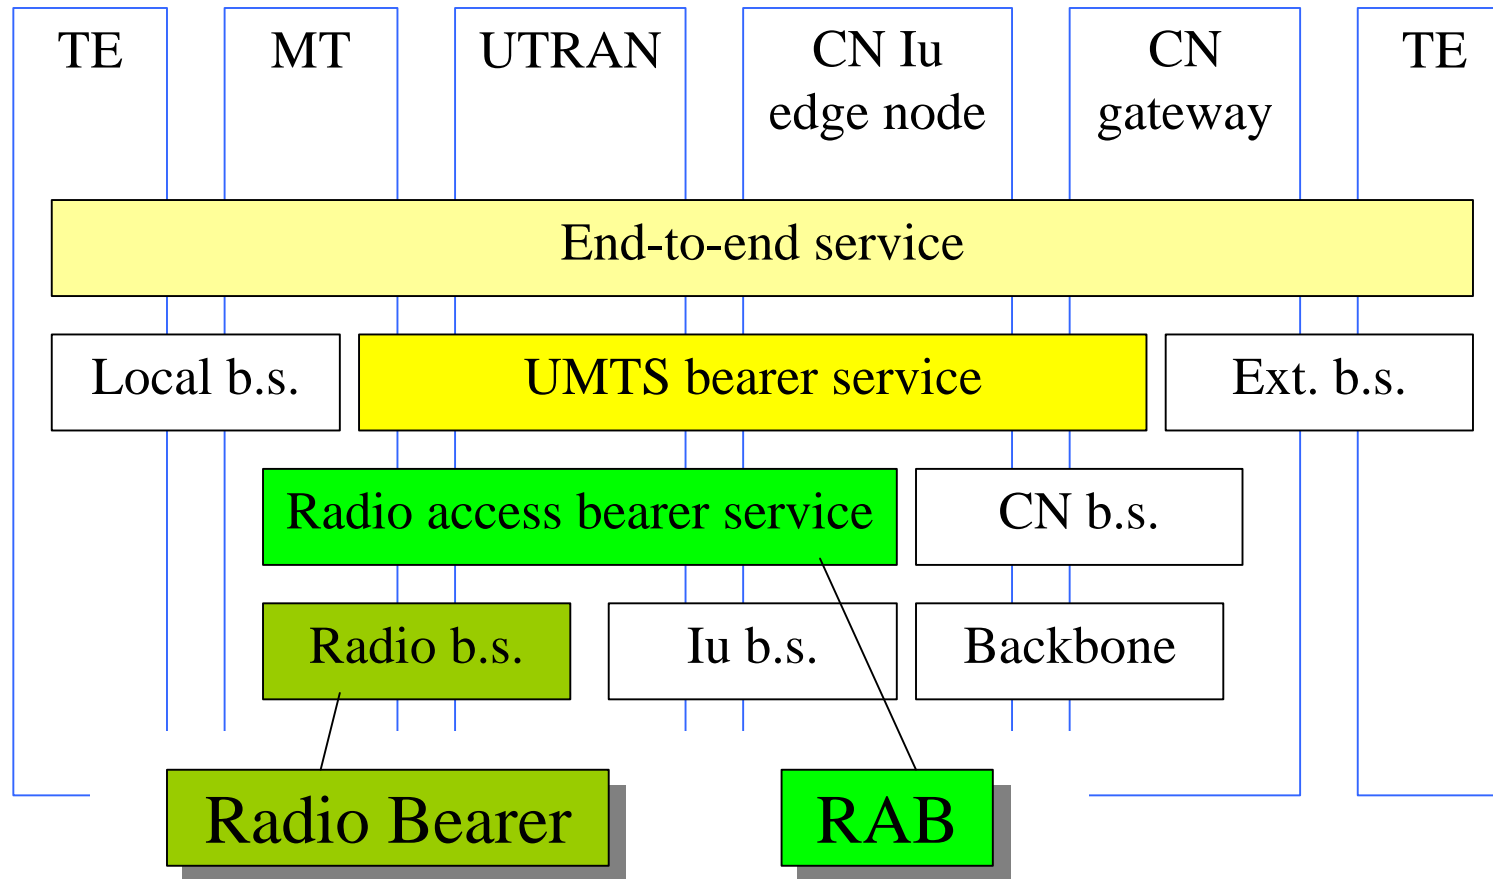

In practice:

*NAS = Non
Access Stratum*

*AS = Access
Stratum*

UMTS bearer service architecture

What is the bearer concept?

Bearer: a bearer capability of defined capacity, delay and bit error rate, etc. (as defined in the 3GPP specs)

Bearer is a flexible concept designating a kind of "bit pipe"

- at a certain network level
- between certain network entities
- with certain QoS attributes, capacity, and traffic flow characteristics

UMTS QoS Classes

- conversational, streaming, interactive, background

Connection-oriented / connectionless **bearer service**

In a **connection oriented** mode, a logical association called *connection* needs to be established between the source and the destination entities before information can be exchanged between them. Connection oriented bearer services lifetime is the period of time between the establishment and the release of the connection.

In a **connectionless** mode, no connection is established beforehand between the source and the destination entities. The source and destination network addresses need to be specified in each message. Transferred information cannot be guaranteed of ordered delivery. Connectionless bearer services lifetime is reduced to the transport of one message.

Four Basic UMTS QoS Classes

Conversational	Streaming	Interactive	Background
low delay	reasonably low delay	low round-trip delay	delay is not critical
low delay variation			
basic QoS requirements			
speech	video streaming	www applications	store-and-forward applications (e-mail, SMS, MMS)
voice over IP	audio streaming		
video conferencing	basic applications		

UMTS protocols

Different protocol stacks for **user** and **control** plane

User plane (for data transport):

circuit switched domain: data within "bit pipes"

packet switched domain: protocols for implementing various QoS or traffic engineering mechanisms

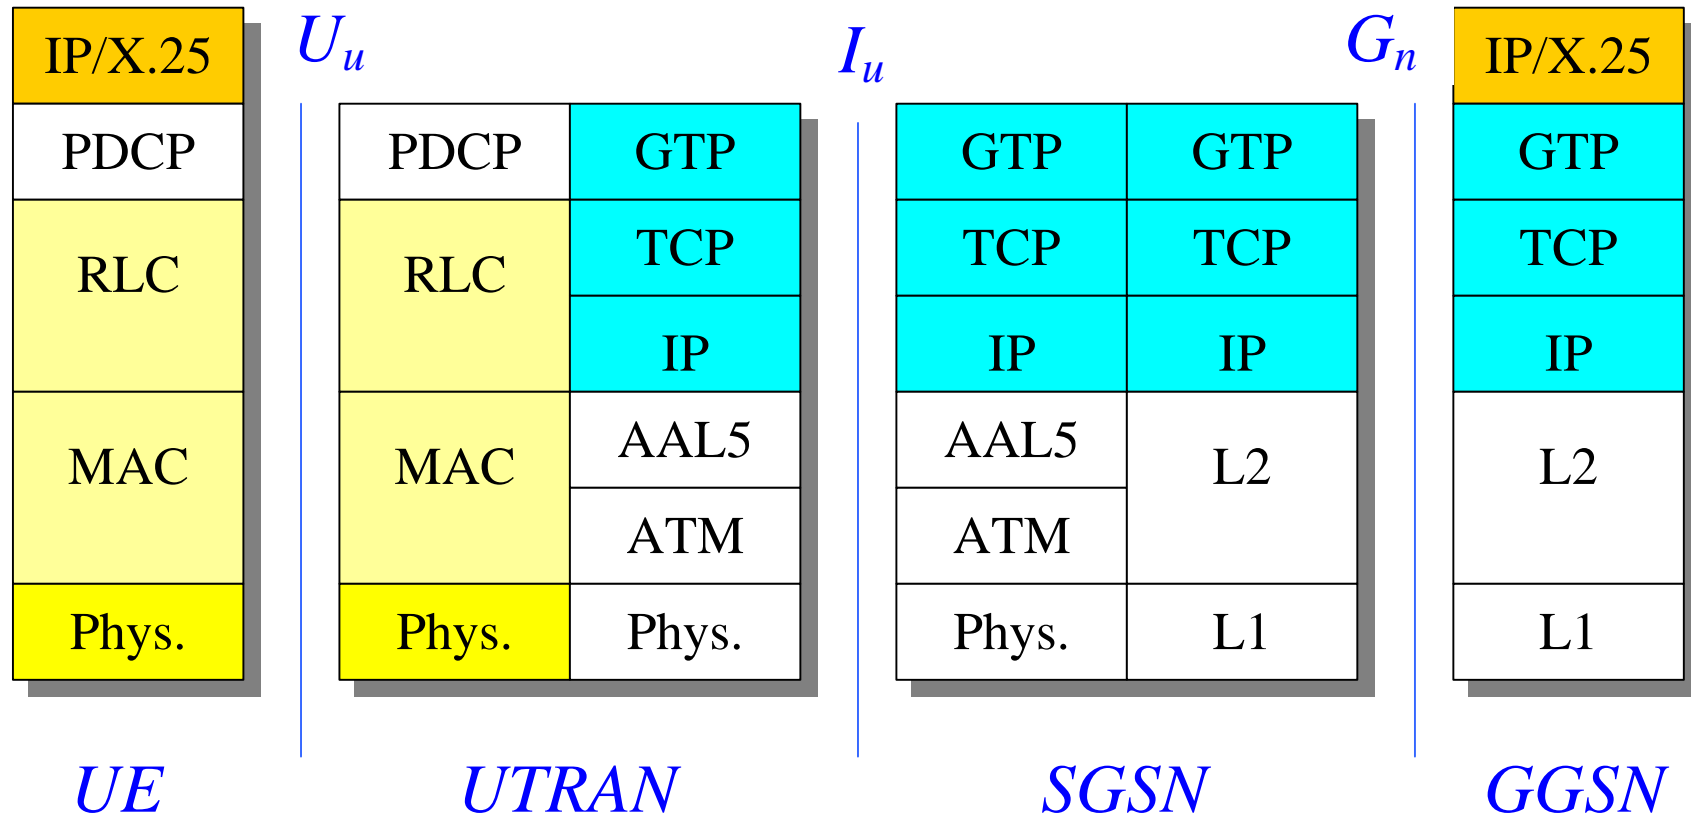

Control plane (for signaling):

circuit switched domain: SS7 based (in core network)

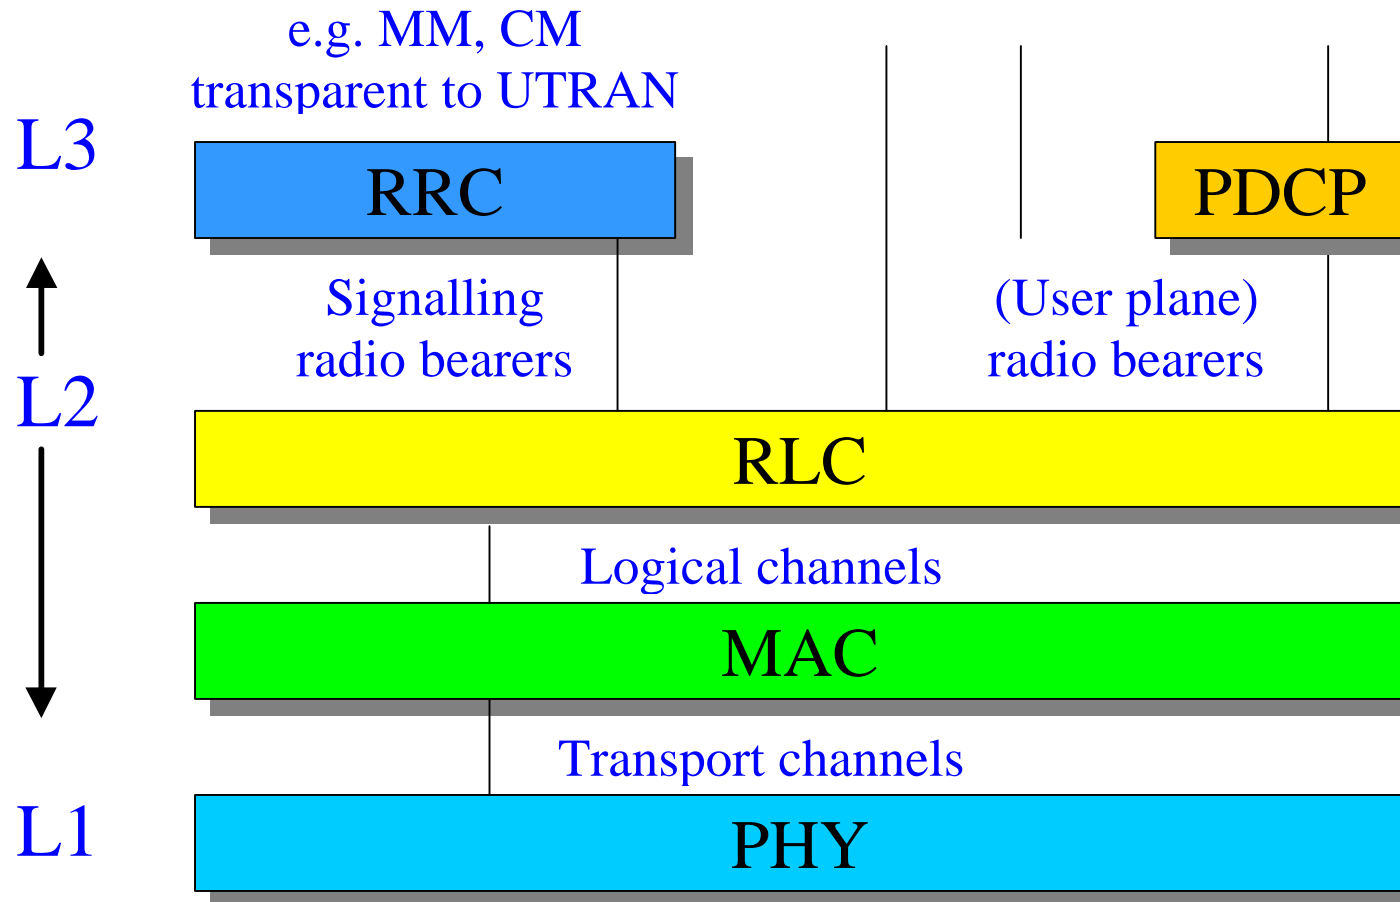

packet switched domain: IP based (in core network)

both domains: UTRAN based (in radio access network)

User plane protocol stacks (PS domain)

Uu interface protocols

Main tasks of Uu interface protocols

MAC (Medium Access Control):

- Mapping between logical and transport channels

RLC (Radio Link Control):

- Segmentation and reassembly
- Link control (flow & error control)

PDCCP (Packet Data Convergence Protocol):

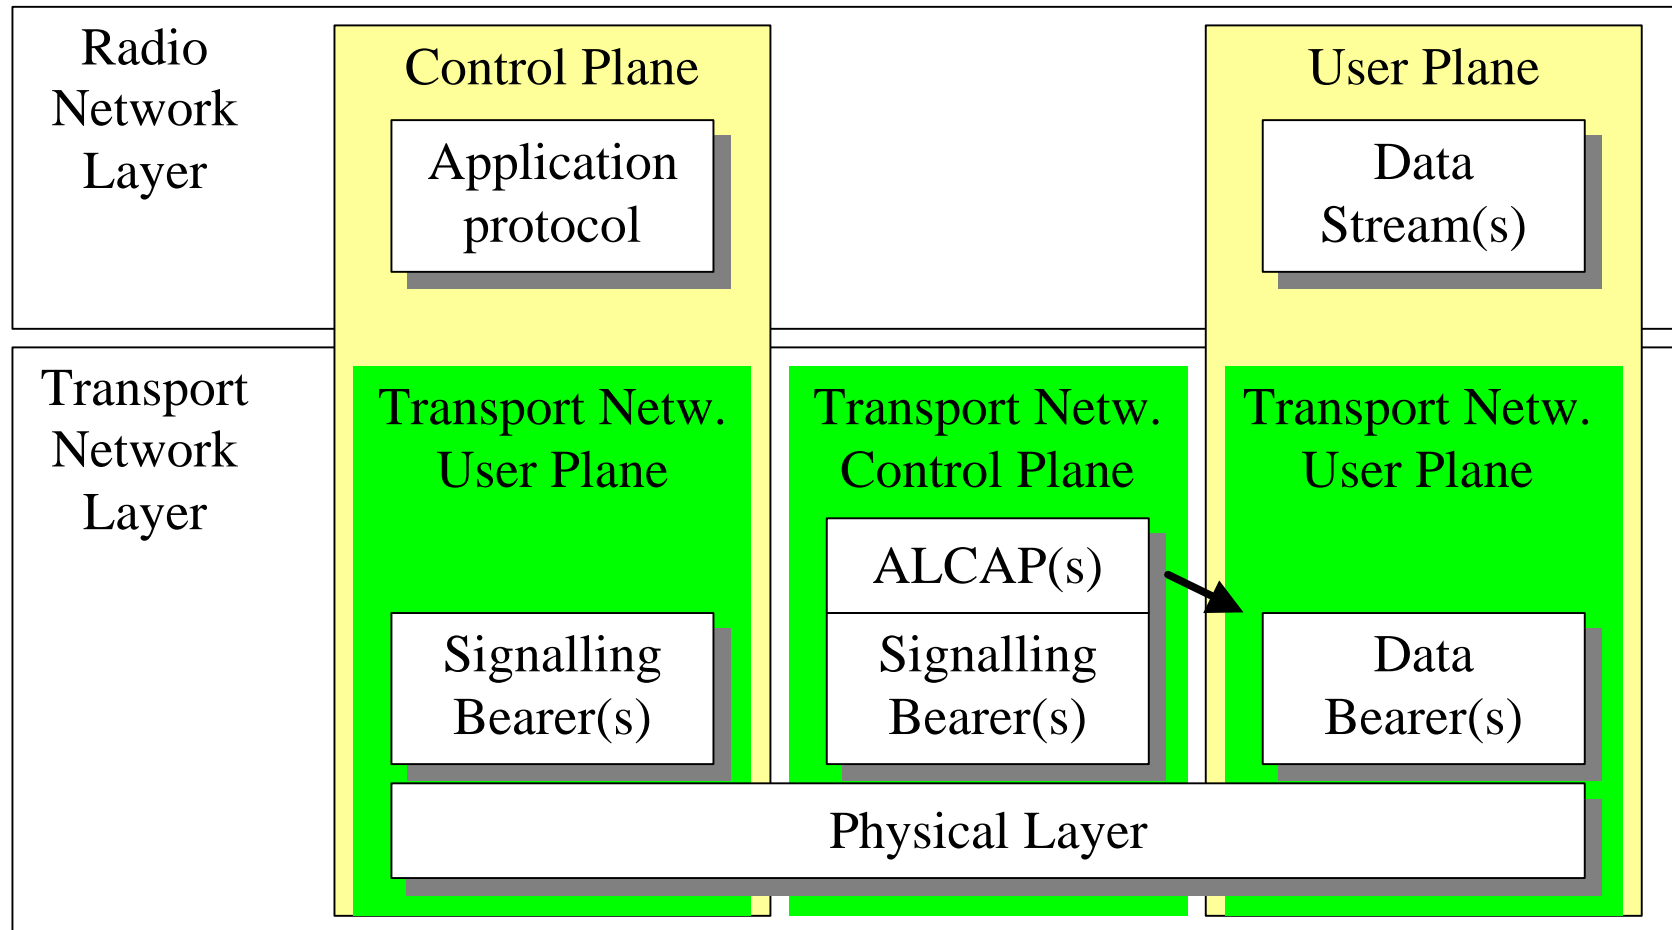

- IP packet header compression (user plane only)

RRC protocol

Over the Uu (air) interface, Radio Resource Control (RRC) messages carry all the relevant information required for setting up, modifying, and releasing **Radio Bearers** between UE and UTRAN. RRC also participates in the coordination of other Radio Resource Management (RRM) operations, such as measurements and handovers.

In addition, RRC messages may carry in their payload higher layer signalling information (MM = Mobility Management, CM = Connection Management, SM = Session Management) that is not related to the air interface or UTRAN.

General protocol model for UTRAN

Control Plane (Iub, Iur and Iu interfaces)

Radio Network Layer: application protocols (NBAP, RNSAP and RANAP) are used for the actual signalling between base stations, RNCs and the core network (CS and PS domains)

Transport Network Layer: signalling bearer for the transport of application protocol messages are set up by O&M actions (in present 3GPP standards: AAL5+Convergence protocols)

Transport Network Control Plane

Used for signalling within the Transport Network Layer and for setting up the data bearer(s)

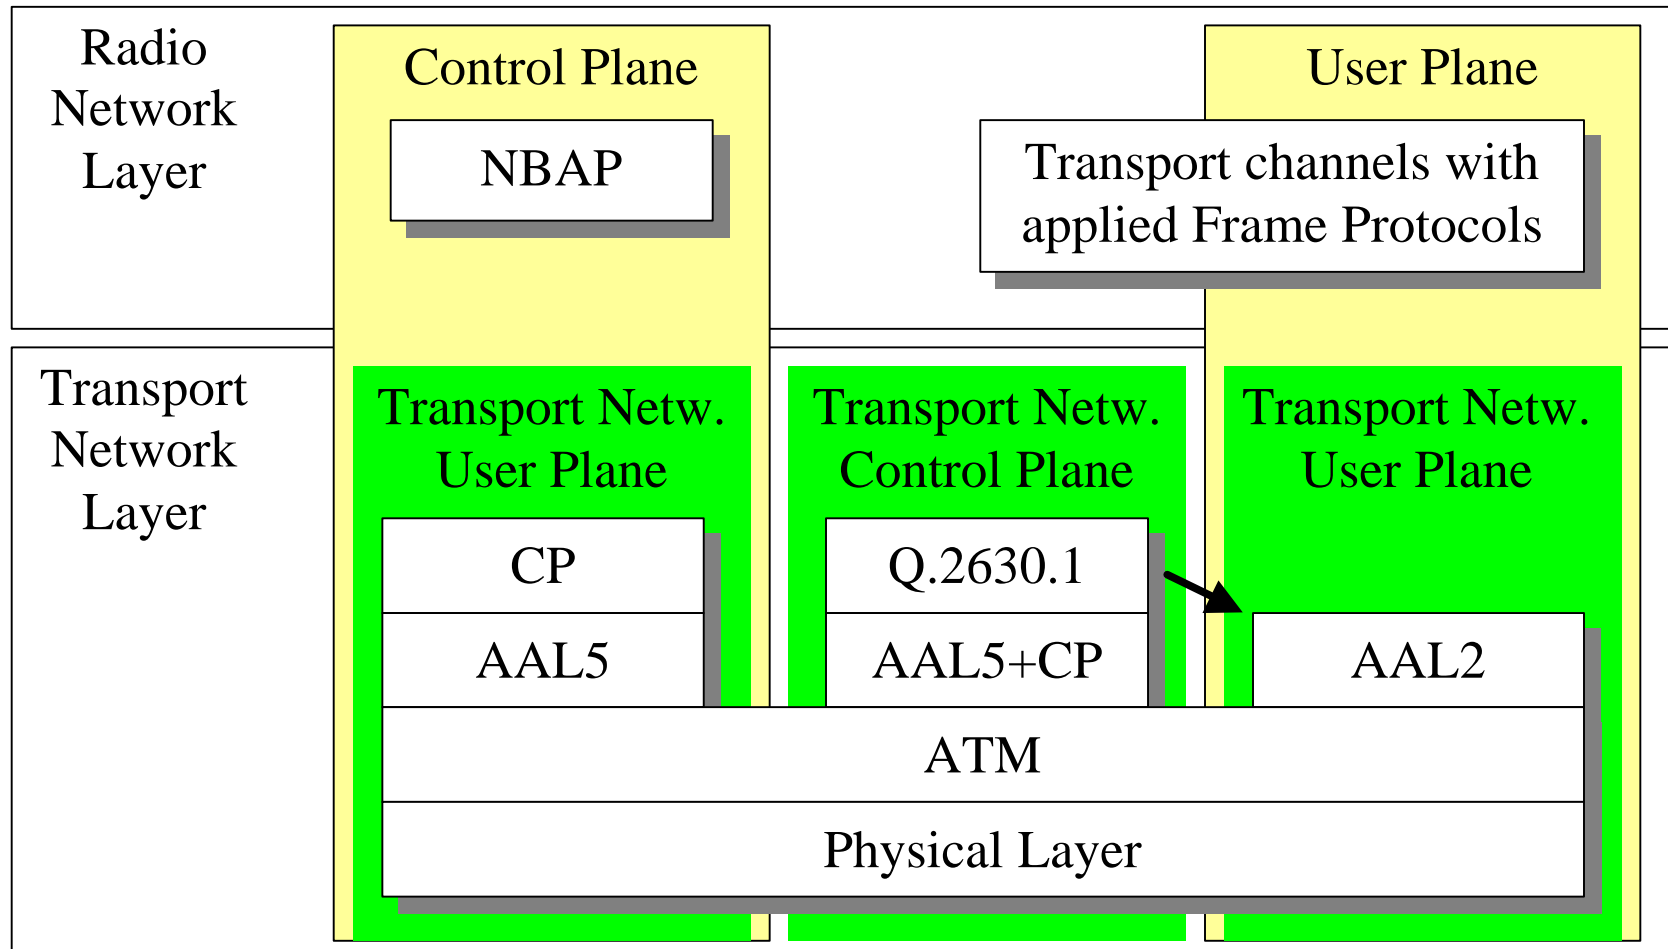

User Plane (Iub, Iur and Iu interfaces)

The User Plane is used for transport of

- user information (circuit switched speech, Internet packets)
- control information packed into various transport channels and sent transparently over radio links

User data streams are carried by data bearers (using AAL2) and may utilize so-called frame protocols (FP) for framing, error control and flow control at the Iub and Iur interfaces

Example (Iub interface)

Application protocols in UTRAN

Iu interface (between RNC and core network)

- **RANAP** (Radio Access Network Application Part)
 - Radio Access Bearer (RAB) management
 - SRNS Relocation
 - Transfer of higher-level signalling messages

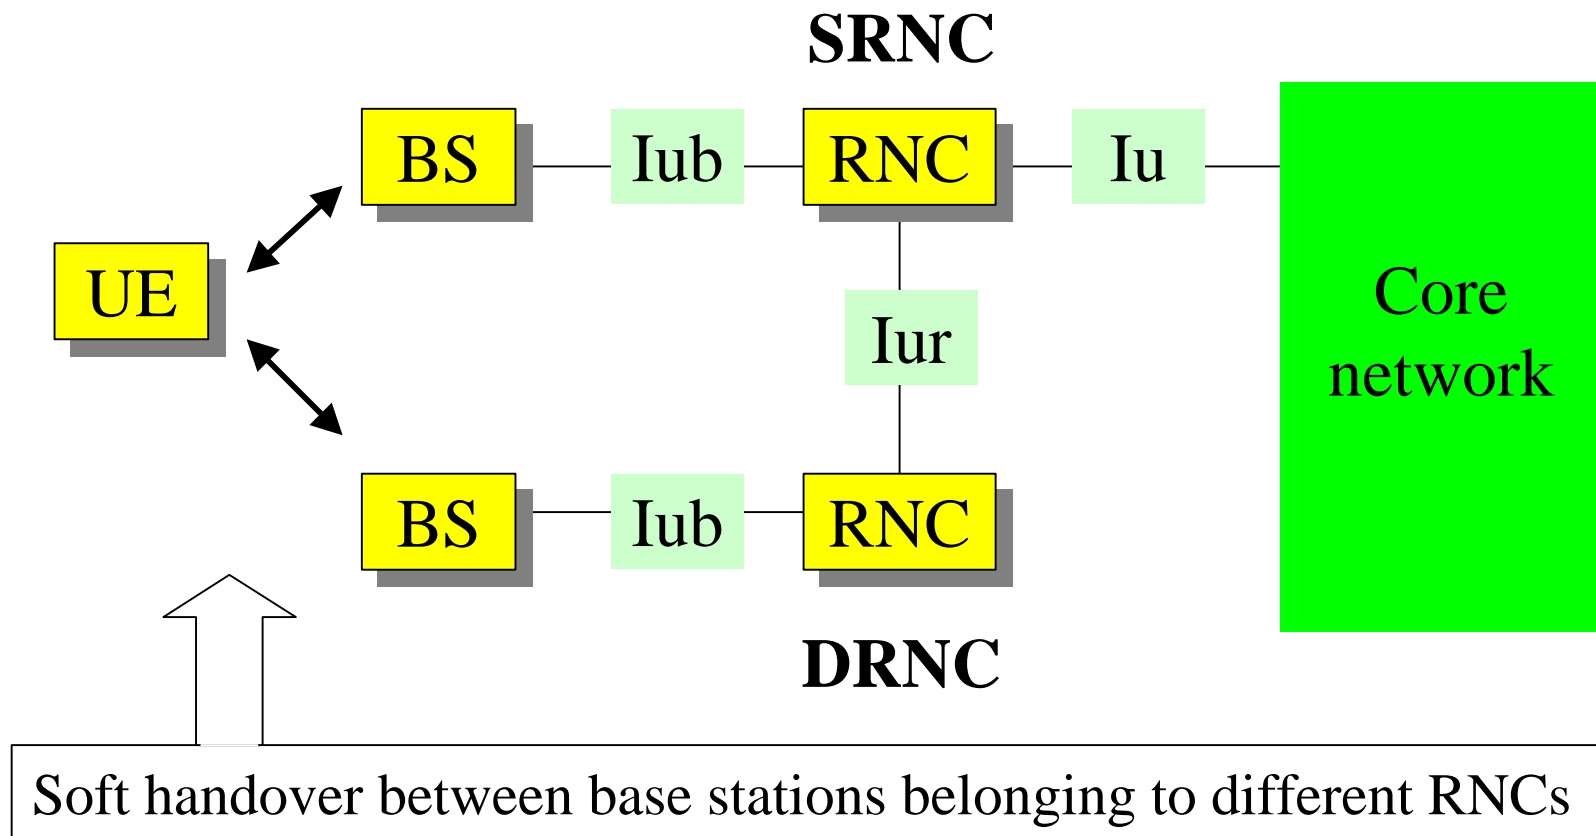

Iur interface (between Serving RNC and Drift RNC)

- **RNSAP** (Radio Network Subsystem Application Part)
 - Link management for inter-RNC soft handover

Iub interface (between RNC and base station)

- **NBAP** (Node B Application Part)

Serving RNC and Drift RNC in UTRAN

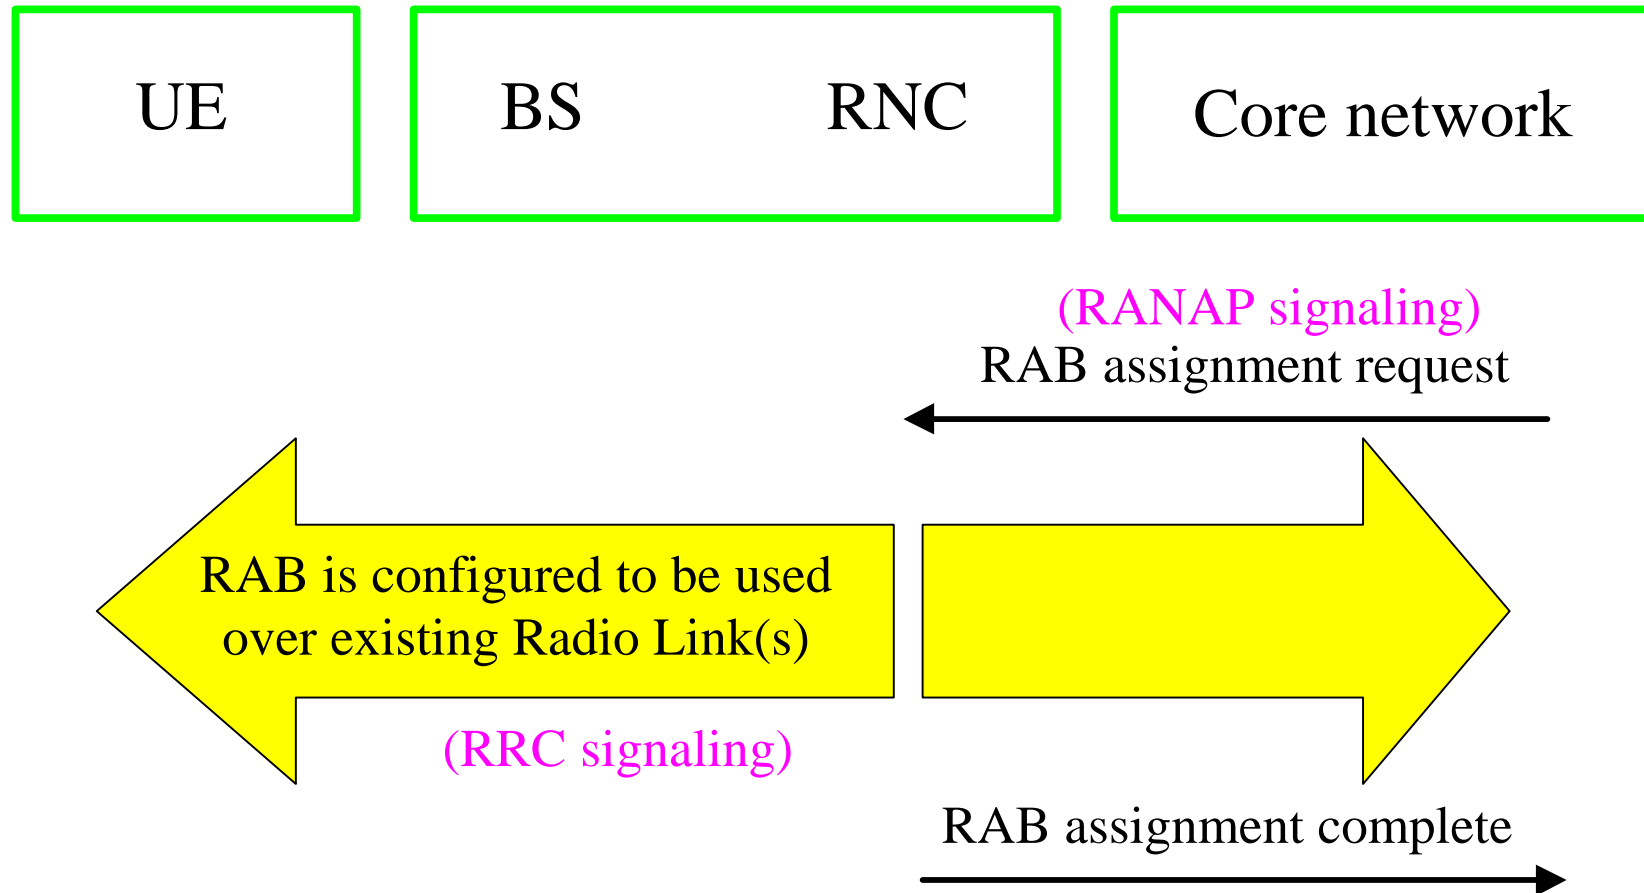

Serving RNS (SRNS) Relocation

RNS = Radio Network Sub-system =
RNC + all base stations controlled by this RNC

SRNS Relocation means that the Serving RNC functionality is transferred from one RNC (the “old” SRNC) to another (the “new” SRNC, previously a DRNC) without changing the radio resources and without interrupting the user data flow.

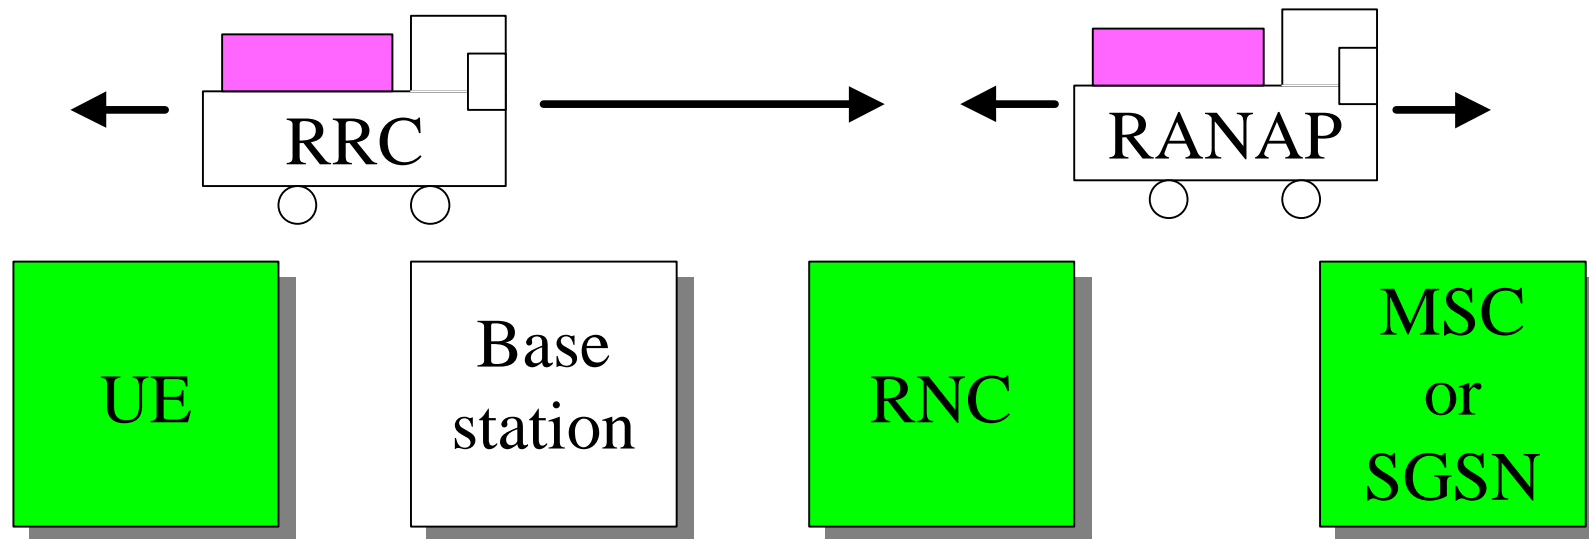

RANAP provides the signalling facilities over the two Iu interfaces involved (Iu interfaces to “old” and “new” SRNC) for performing SRNC Relocation in a coordinated manner.

Radio Access Bearer (RAB) establishment

Signalling between UE and Core network

NAS signalling messages (NAS = non access stratum = “not related to UTRAN”) are sent transparently through UTRAN in the payload of RRC and RANAP protocol messages

Logical / Transport / Physical channels

(DCH transport channel is taken as example)

Logical channels

Transport channels

Logical channels

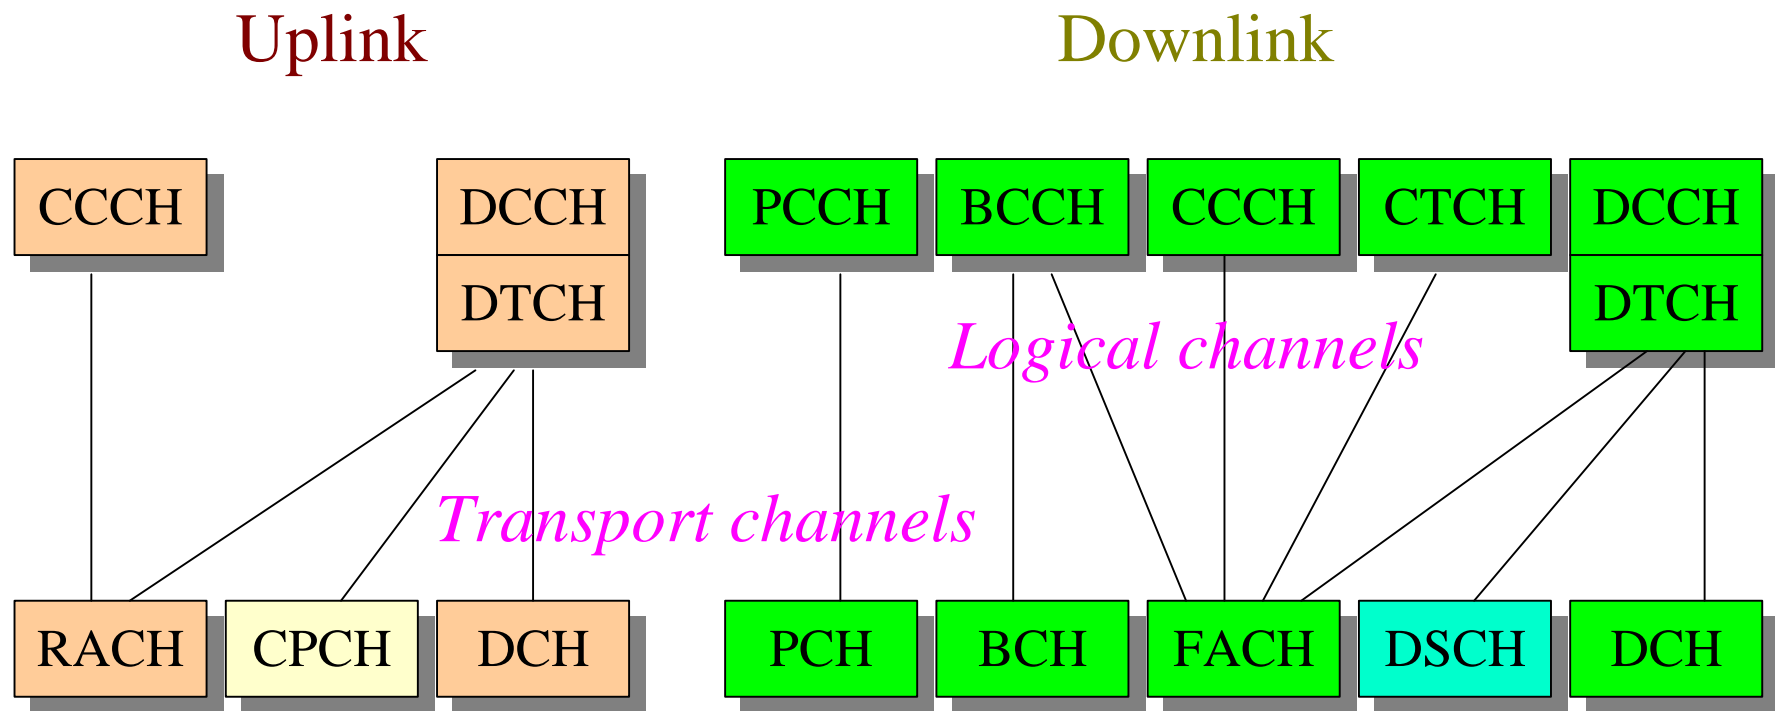

Physical channels

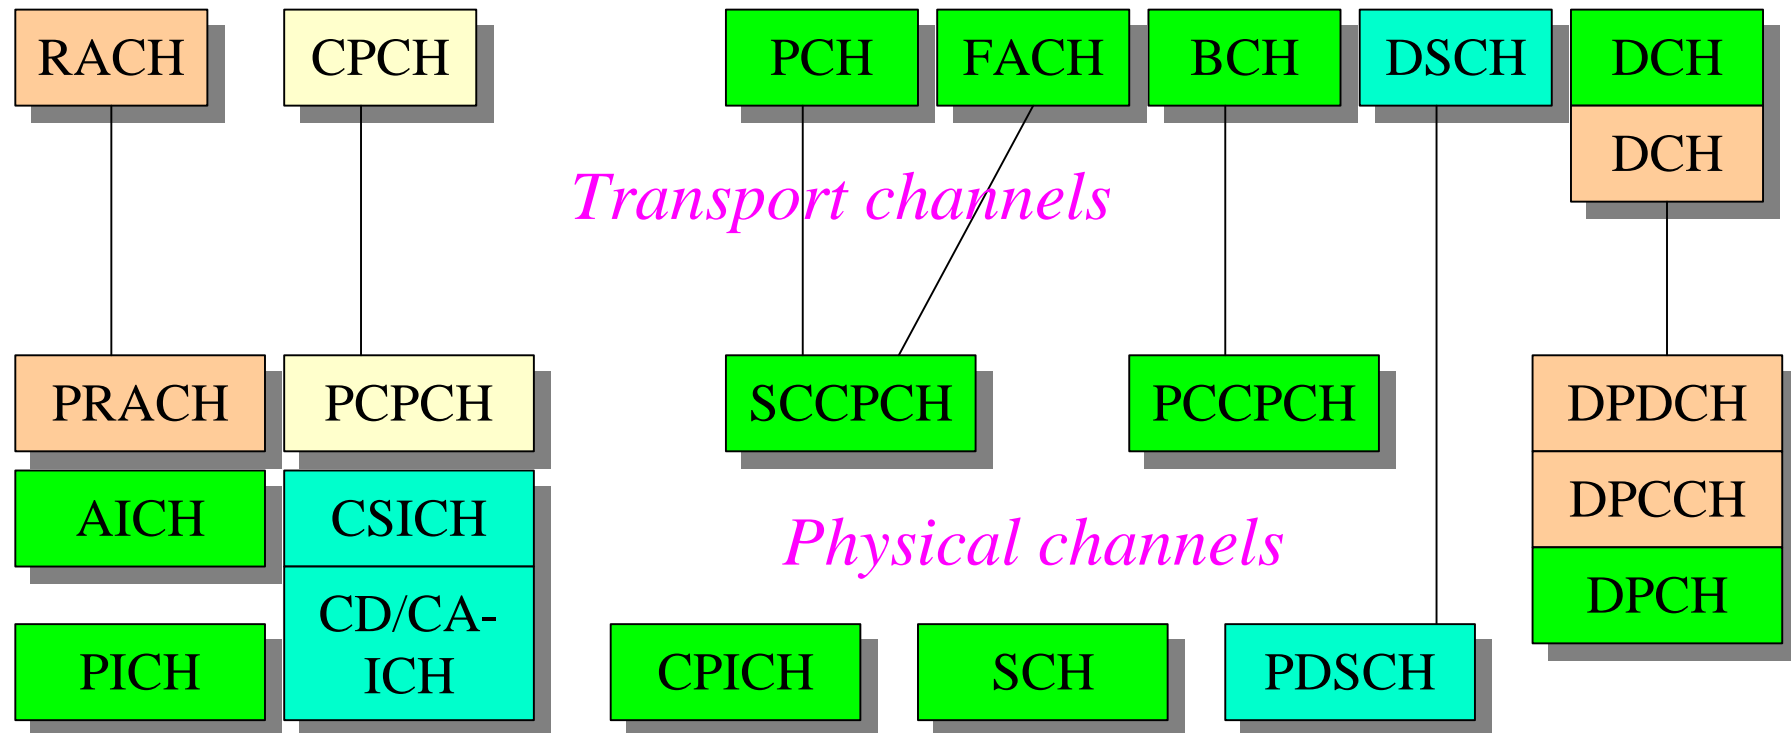

Significance for WCDMA air interface only

Logical channels \Leftrightarrow Transport channels

Transport channels \Leftrightarrow Physical channels

Physical channels in WCDMA

Bit sequences in different physical channels are modulated using different spreading codes, which are **code multiplexed**

$$\text{spreading code} = \text{channelization code} \times \text{scrambling code}$$

Downlink channels: conventional QPSK modulation

DPCH = Dedicated physical channel

Uplink channels: Dual-channel QPSK modulation

DPDCH = Dedicated physical data channel

DPCCH = Dedicated physical control channel

DPCH structure in downlink

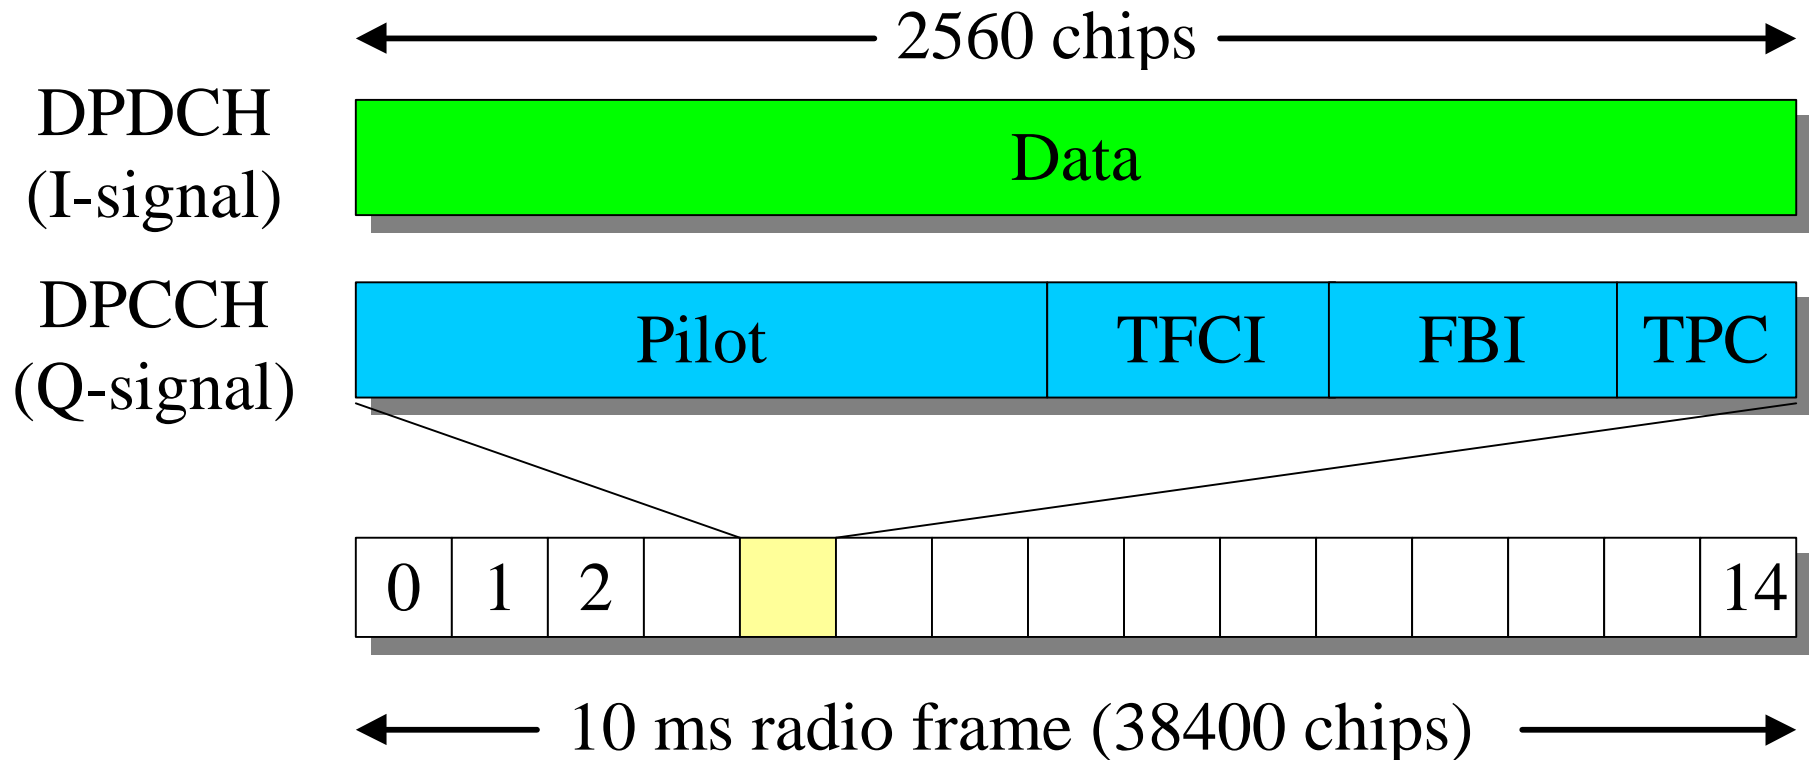

QPSK modulation,

time multiplexed data and control information:

DPDCH / DPCCH structure in uplink

Dual-channel QPSK modulation:

Spreading in WCDMA

spreading code = channelization code \times scrambling code

Channelization (Walsh-Hadamard) codes: different codes are **completely orthogonal** if used for synchronous multiplexing

After scrambling, the spreading codes are **near orthogonal** even when not synchronized (multipath transmission)

Usage of code	uplink	downlink
Channelization code		user separation
Scrambling code	user separation	cell separation

Spreading facts

Chip rate after spreading = 3.84 Mchips/s

Spreading factor (SF) is important in WCDMA

Chip rate = SF \times channel bit rate

Uplink: DPCCH SF = 256, DPDCH SF = 4 - 256

Downlink: DPCH SF = 4 - 512

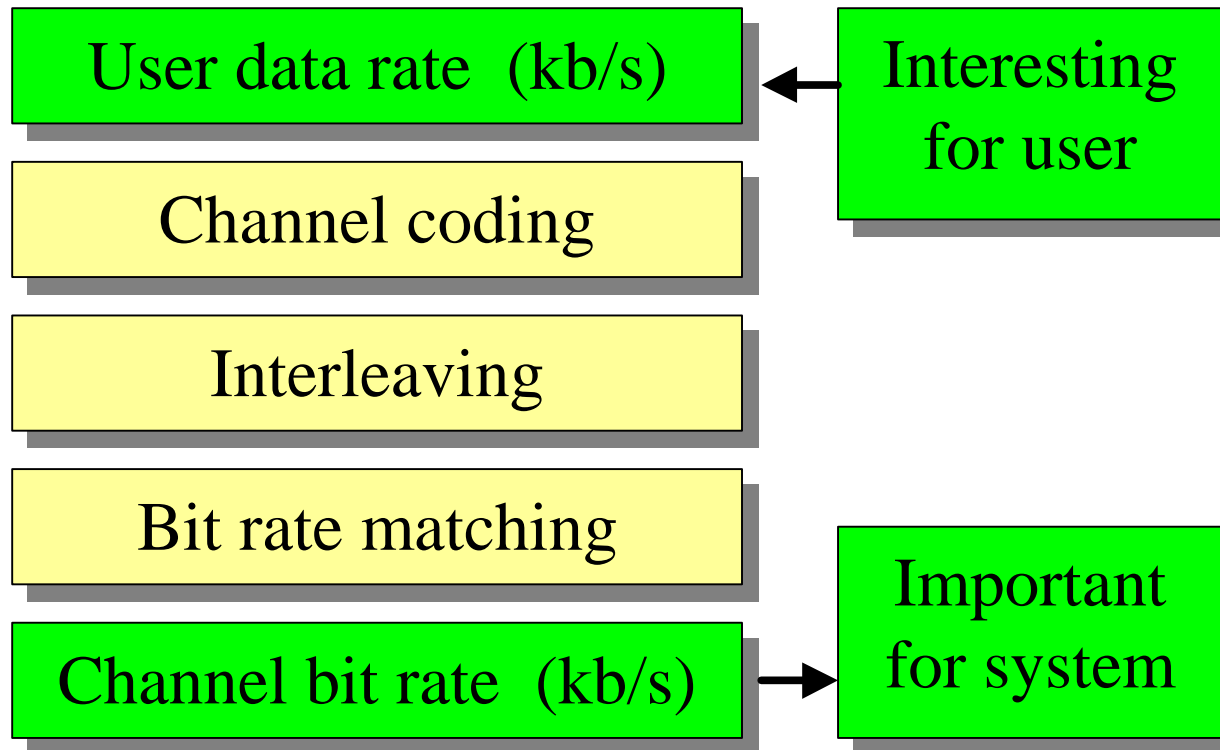

Uplink DPDCH data rates

SF	Channel bit rate (kb/s)	User data rate (kb/s)
256	15	approx. 7.5
128	30	approx. 15
64	60	approx. 30
32	120	approx. 60
16	240	approx. 120
8	480	approx. 240
4	960	approx. 480

Downlink DPCH data rates

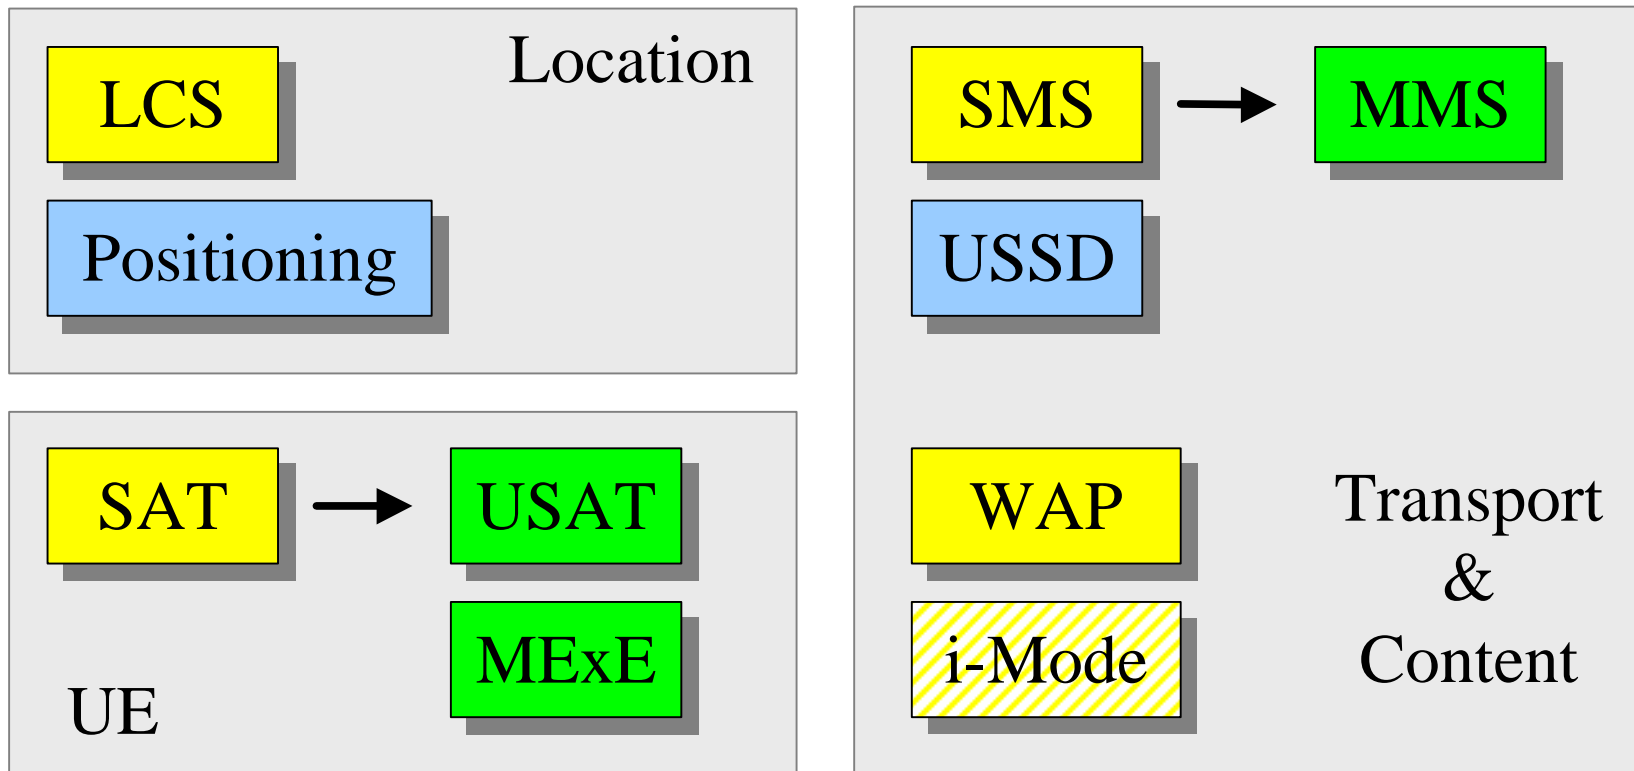

SF	Channel bit rate (kb/s)	User data rate (kb/s)
512	15	approx. 1-3
256	30	approx. 6-12
128	60	approx. 20-24
64	120	approx. 45
32	240	approx. 105
16	480	approx. 215
8	960	approx. 456
4	1920	approx. 936

User data rate vs. channel bit rate

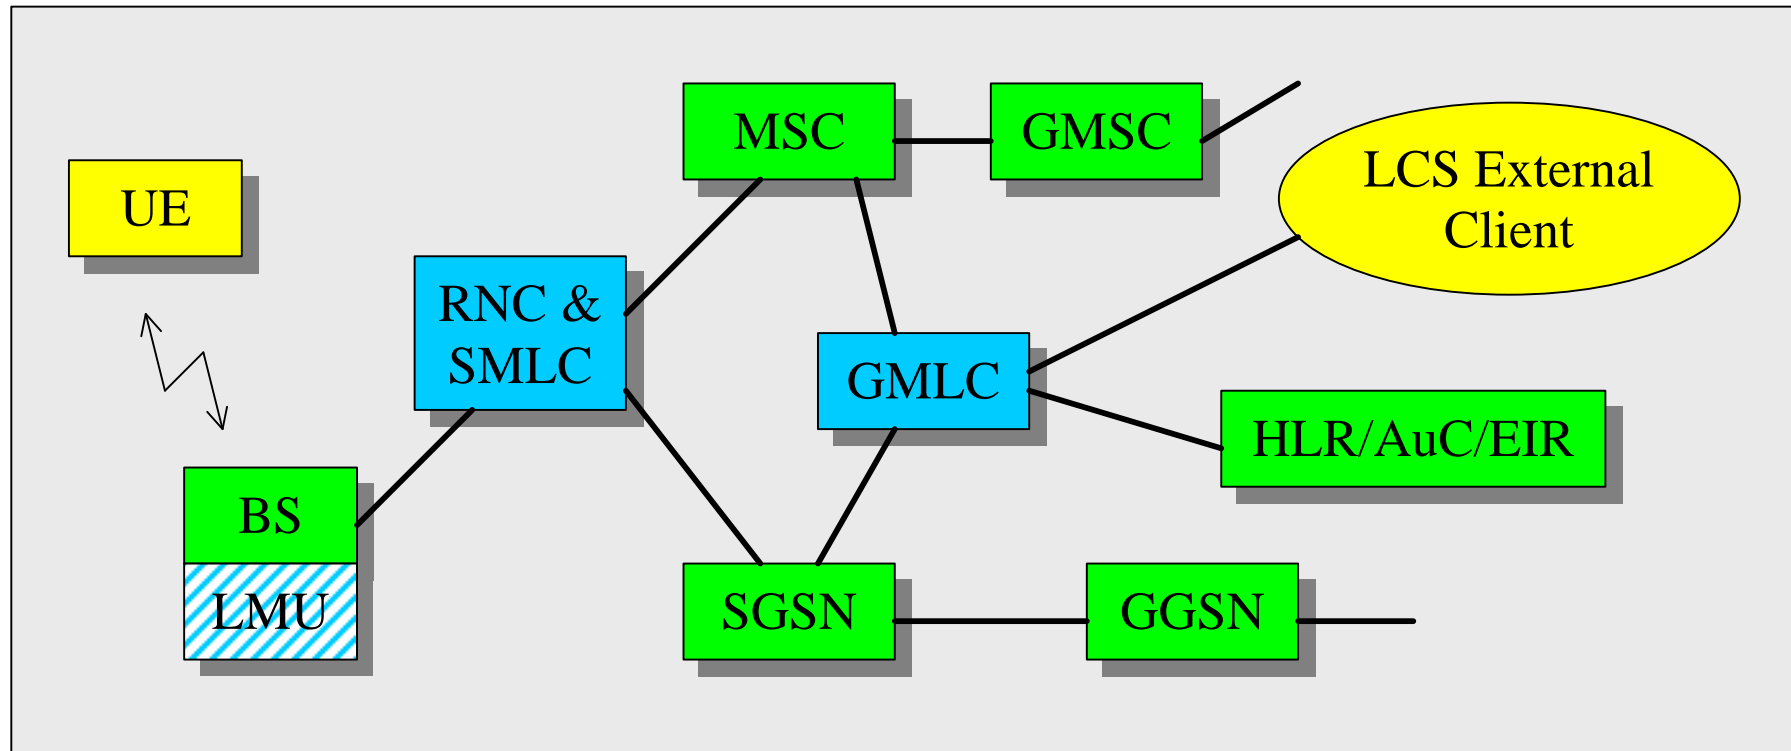

Supporting technologies and services

- most are already possible in 2G
- will be extensively used in 3G

Location (based) services (LCS)

- may or may not make use of UE positioning techniques
- general LCS architecture in UMTS:

LCS cont.

GMLC = Gateway Mobile Location Center

- receives service requests from external LCS clients (or UE) and manages the location information

SMLC = Serving Mobile Location Center

- assists in positioning of the UE (e.g. performs calculations based on measurement results)

LCS client = typically any server requesting location information (to be able to provide the relevant location-dependent service to the user)

Positioning Methods

Cell ID based location information

- no expensive positioning solutions required
- inexpensive (and will therefore be widely used)

E-OTD (2G), OTDOA (3G)

- differential delays measured from which the position is calculated (in SMLC)

Assisted GPS

- greatest precision, expensive GPS terminals
- network must “assist” in indoor environment

SAT (= USAT in 3G)

SAT (SIM Application Toolkit) is a set of standardized functions for communication between SIM and ME

Applications (GSM 11.14):

- profile download (ME tells SIM what it can do)
- proactive SIM (display text from SIM to ME, send short message, transfer info from ME to SIM,...)
- call control by SIM
- data download from network to SIM

download (e.g. Java applets) from server in network will be important in UMTS

MExE

Mobile Execution Environment provides several standardized application execution environments for UE, such as

MExE Classmark 1: UE is WAP compatible (i.e. contains WAP browser)

MExE Classmark 2: UE can execute PersonalJava applications (subset of J2SE)

MExE Classmark 3: UE is J2ME compatible

Micro Edition Standard Edition

:

see: www.mexeforum.org

SMS vs. USSD

SMS = Short Message Service

USSD = Unstructured Supplementary Services Data

SMS

- 160 ASCII characters (max)
- in all GSM terminals
- store-and-forward (=> delay)
- transport of messages
- SMS transaction always initiated by terminal

very popular

USSD

- 182 ASCII characters (max)
- in all GSM terminals
- connection oriented signaling
- transport of technical data
- terminal or application in network initiates session

not much used (yet)

MMS

MMS = Multimedia Messaging System

Offers the ability to send messages to MMS capable handsets comprising a combination of

- text
- sounds
- images
- video

using GPRS or 3G packet transport.

Intermediate solution EMS = Enhanced Messaging System ?

WAP

WAP = Wireless Application Protocol

Transports WML (Wireless Markup Language) information between terminal and WAP Gateway (using own protocols)

WML is a subset of XML (Extensible Markup L.)

e.g. WTP (similar functionality as HTTP)

SMS, USSD, CSD, GPRS, 3G packet transport ...

Service interaction example

3G subscriber is hungry and asks for a list of nearby located restaurants (from appropriate “Internet Server”).

Network scenario:

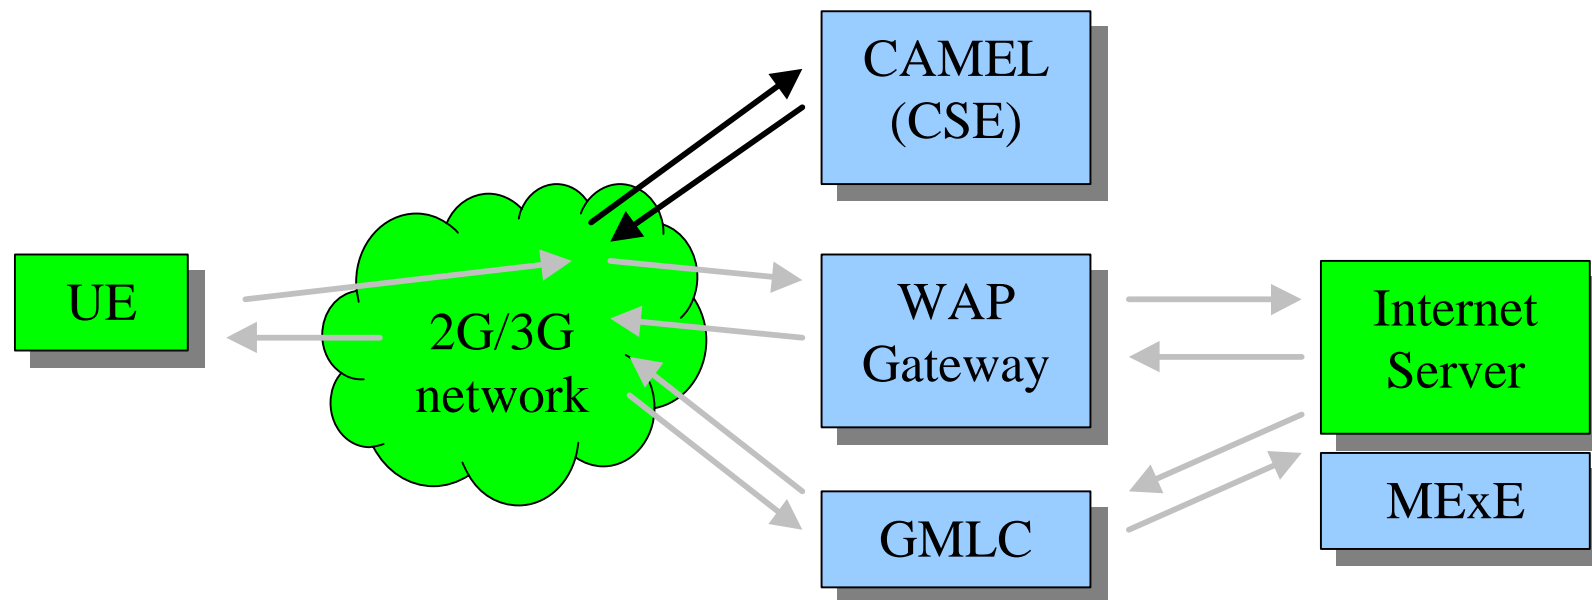

Example, step 1

By use of his/her WAP browser, user contacts (partly using WAP) the “Internet Server” containing relevant information.

Example, step 2

The 2G/3G network retrieves subscription information (e.g. state of “prepaid” account) from the user’s CSE.

Example, step 3

“Internet Server” acts as a “LCS client” and requests the 2G/3G network to investigate where the user is located.

Example, step 4

MExE compatible “Internet Server” prepares the information according to MExE capabilities of UE.

Example, step 5

Now the “local restaurants” information is downloaded to the user and displayed in the appropriate form.
